

## Introduction

- Under the context of health system fragmentation (HSF), health services, resources, and care organizations have limited coordination and collaboration.
- This leads to inefficiencies and inequalities that manifest in suboptimal patient care.
- Maternal mortality ratio (MMR) is a sensitive metric reflecting healthcare system performance.

## Objective

- To analyze the temporal and territorial evolution of MMR during 2000-2021 in Mexico and its potential relationship with health system fragmentation.

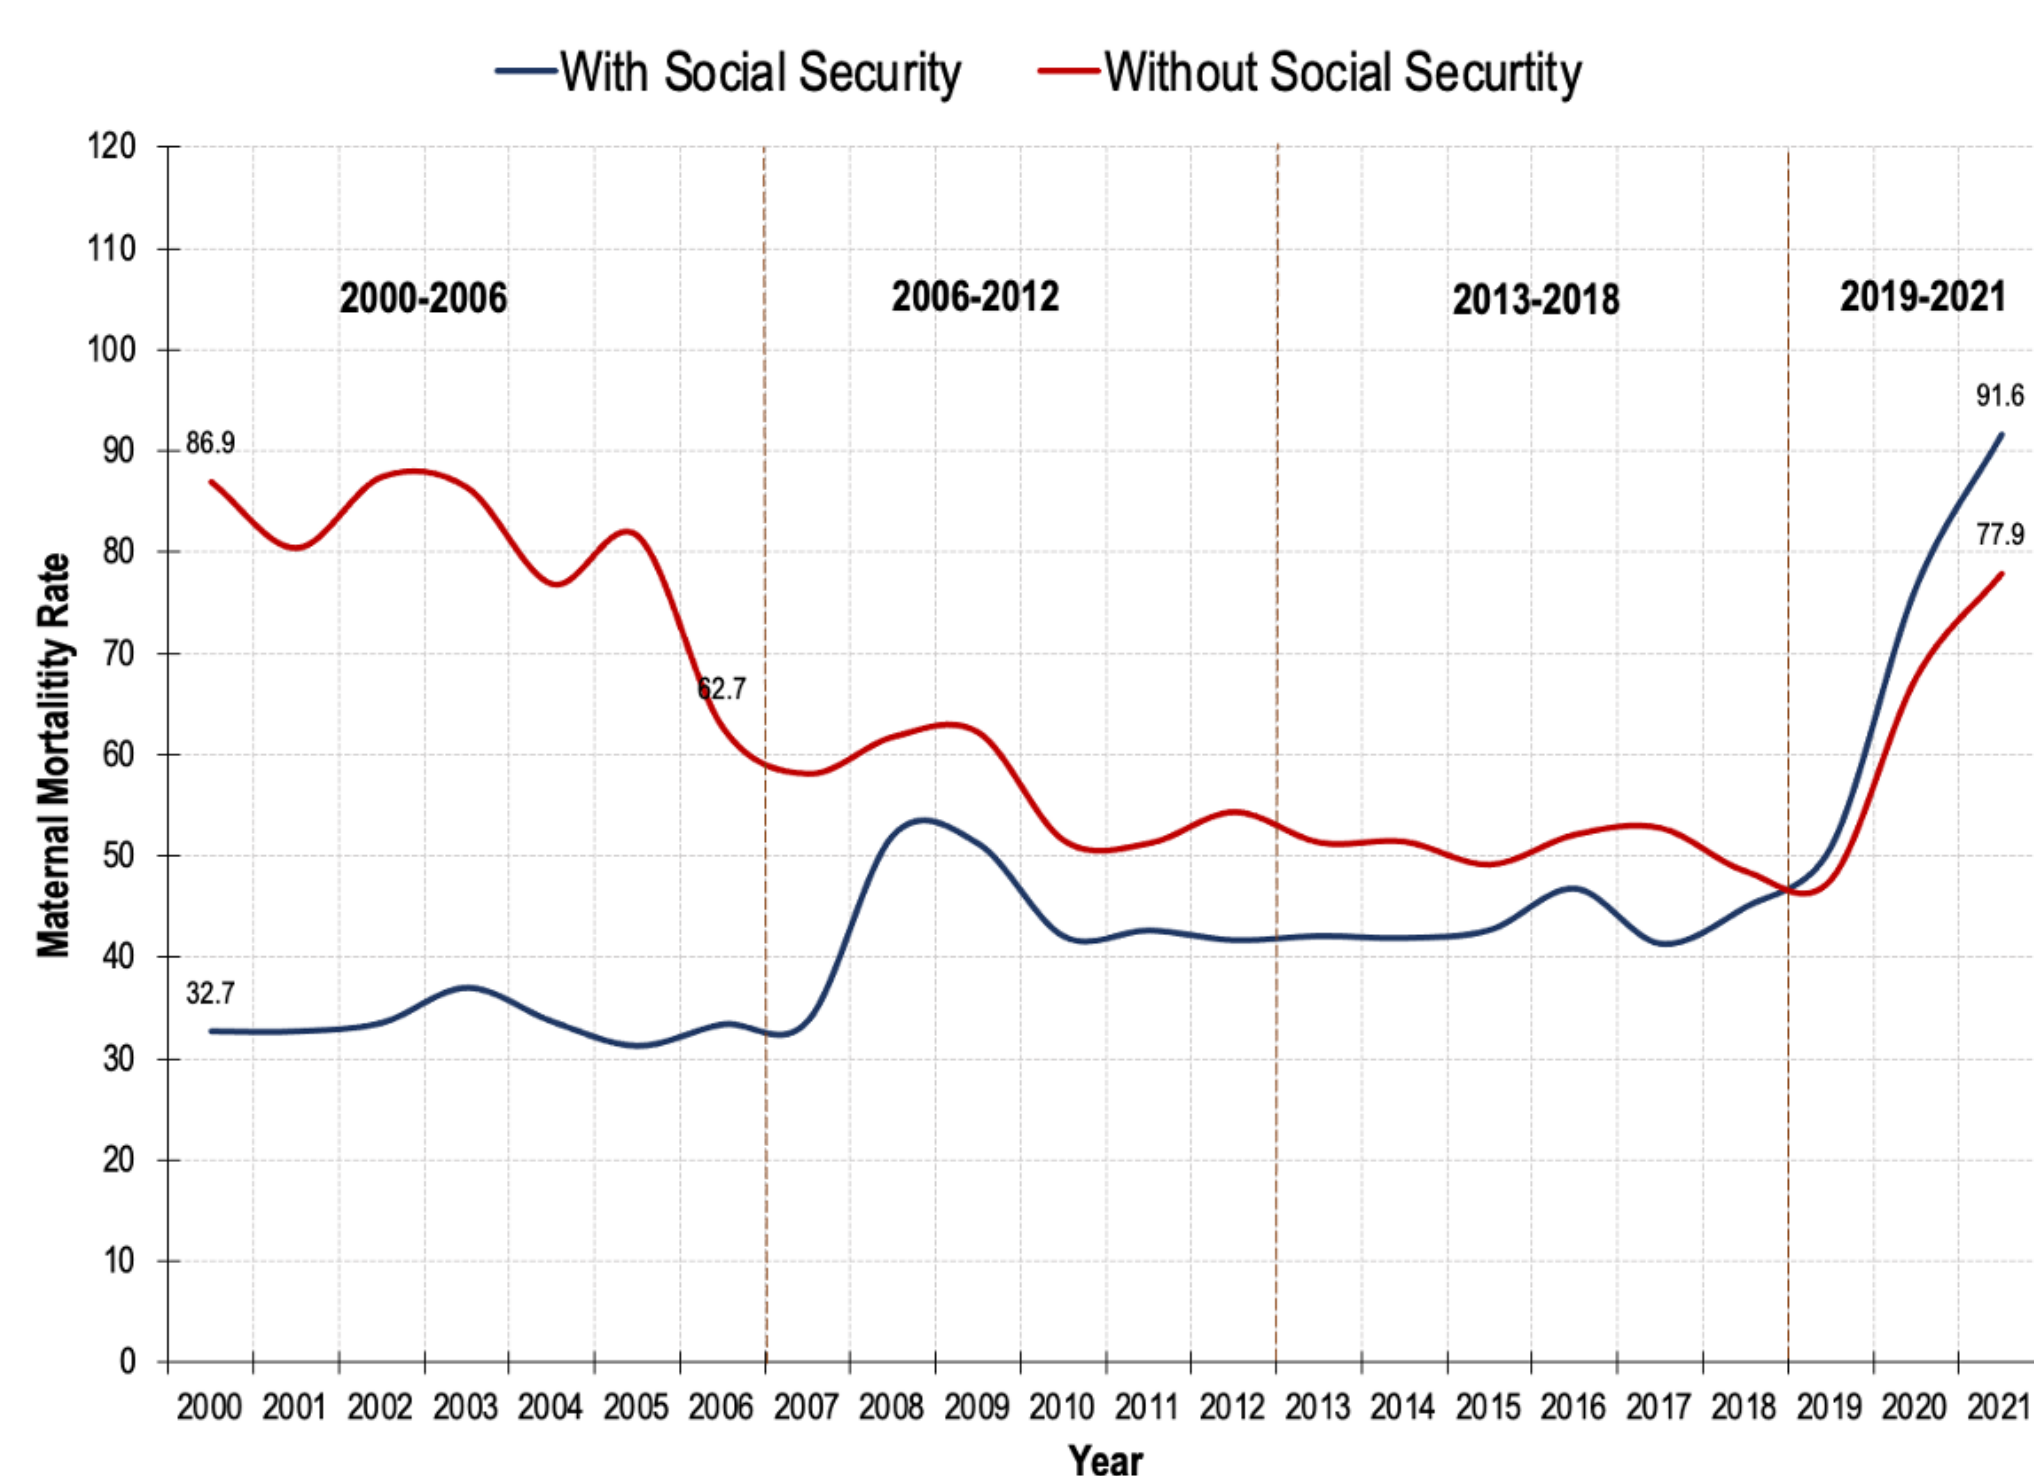

## Methods

- We used the official mortality records published by the Mexican government.
- We identified maternal deaths (MDs) in women 10 to 54 years of age using the ICD-10 as reference.
- Two comparative analyses were conducted to identify the sociodemographic profiles over-represented first compared MDs with women who survived obstetric events. The second compared MDs in women with and without social security.
- MMRs were estimated at the state and national levels to analyze the trends, and gaps between populations with and without social security and their historical evolution over the past two decades.

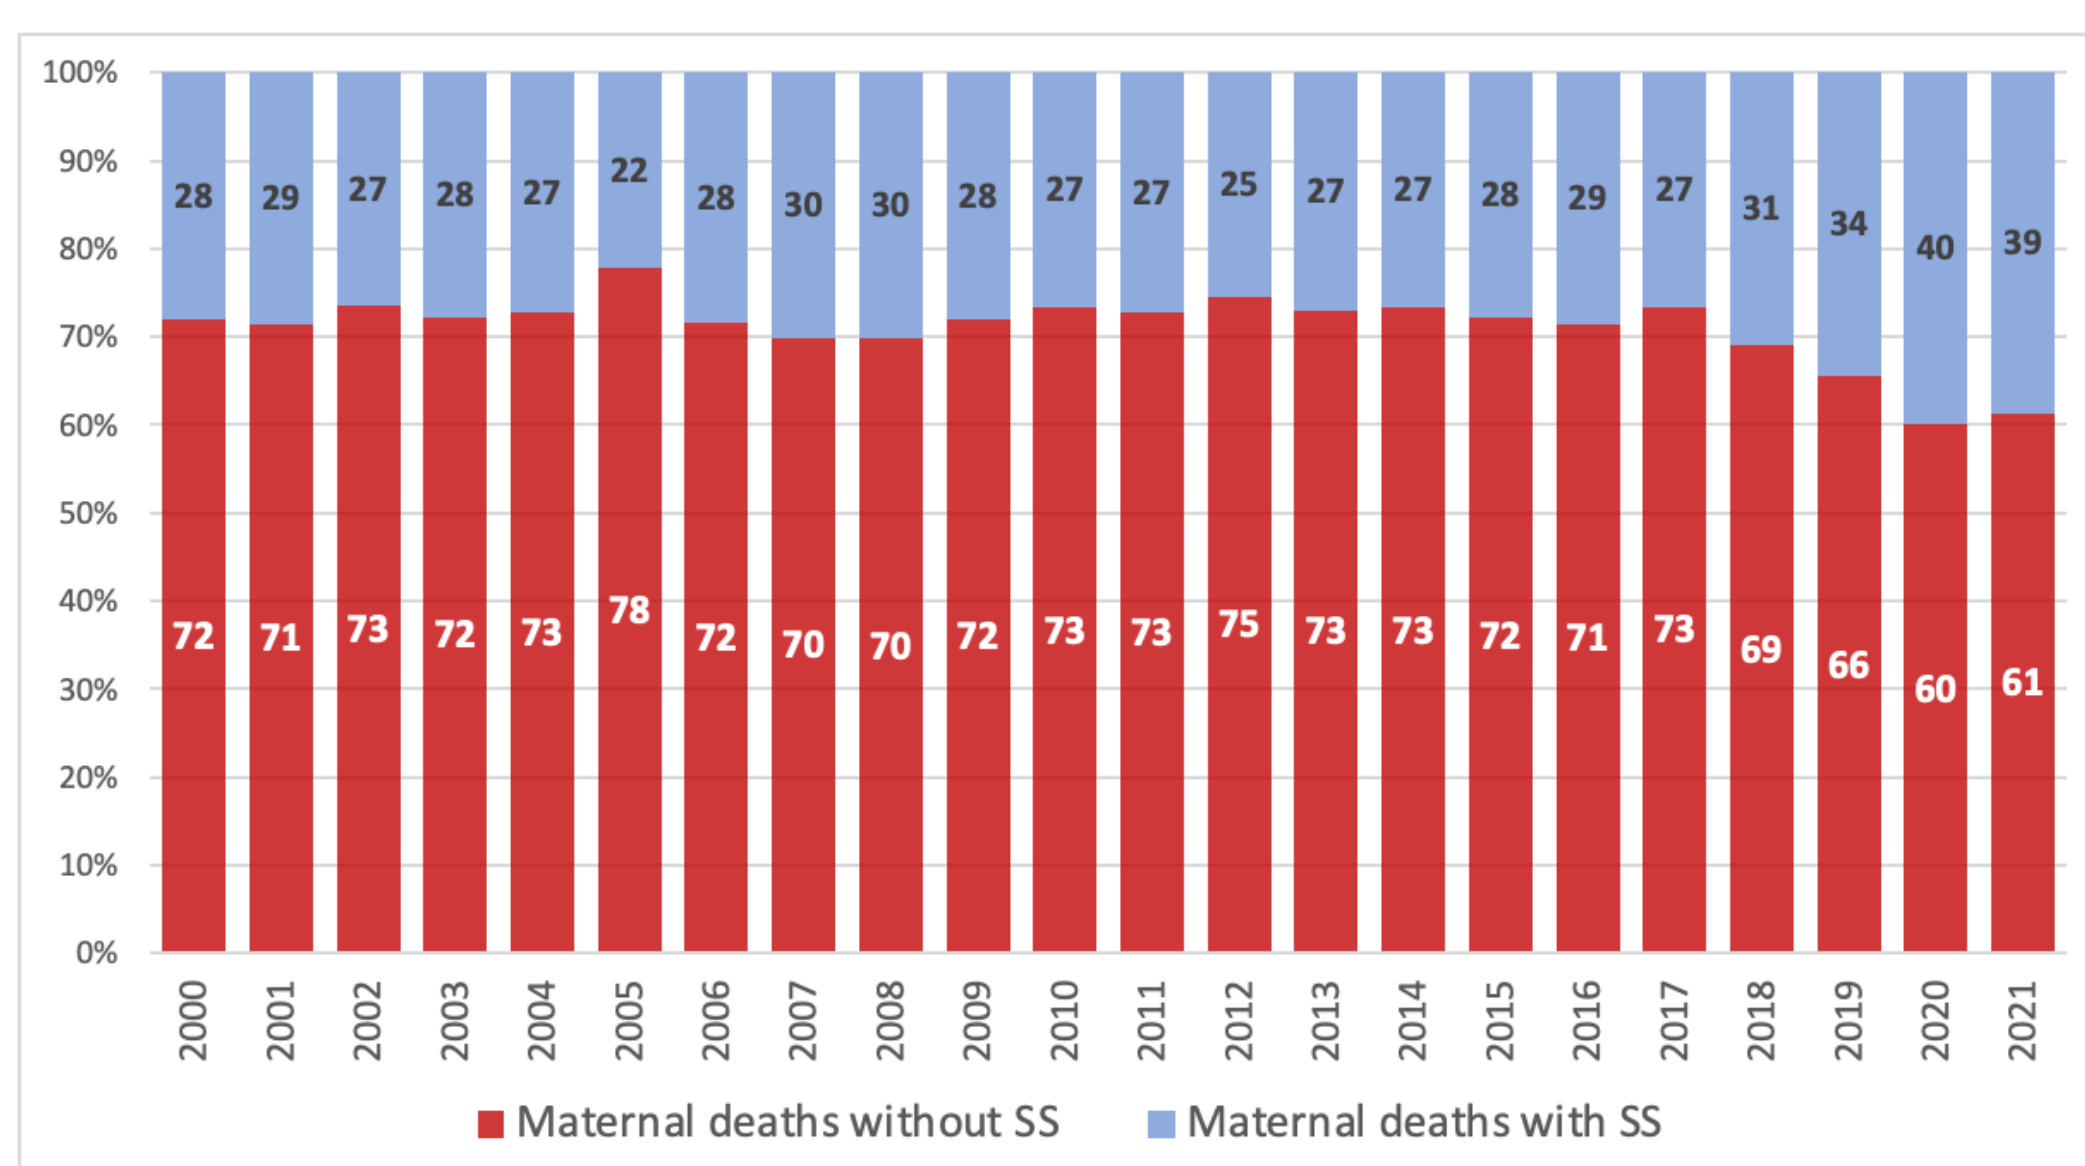

## Results

- In both comparisons there was an over-representation of MDs among women with **no or primary education, unmarried, who did not receive institutional care, residing in rural areas with a higher presence of indigenous population, and in municipalities with a high degree of marginalization**
- We observed a decrease in the national trend in MMR among the population without social security (from 86 to 48) in the period 2000-2018 and an increase in the population with social security (from 33 to 45) in the same period.

**Fig 1. Maternal mortality ratio by social security status in Mexico from 2000 to 2021**

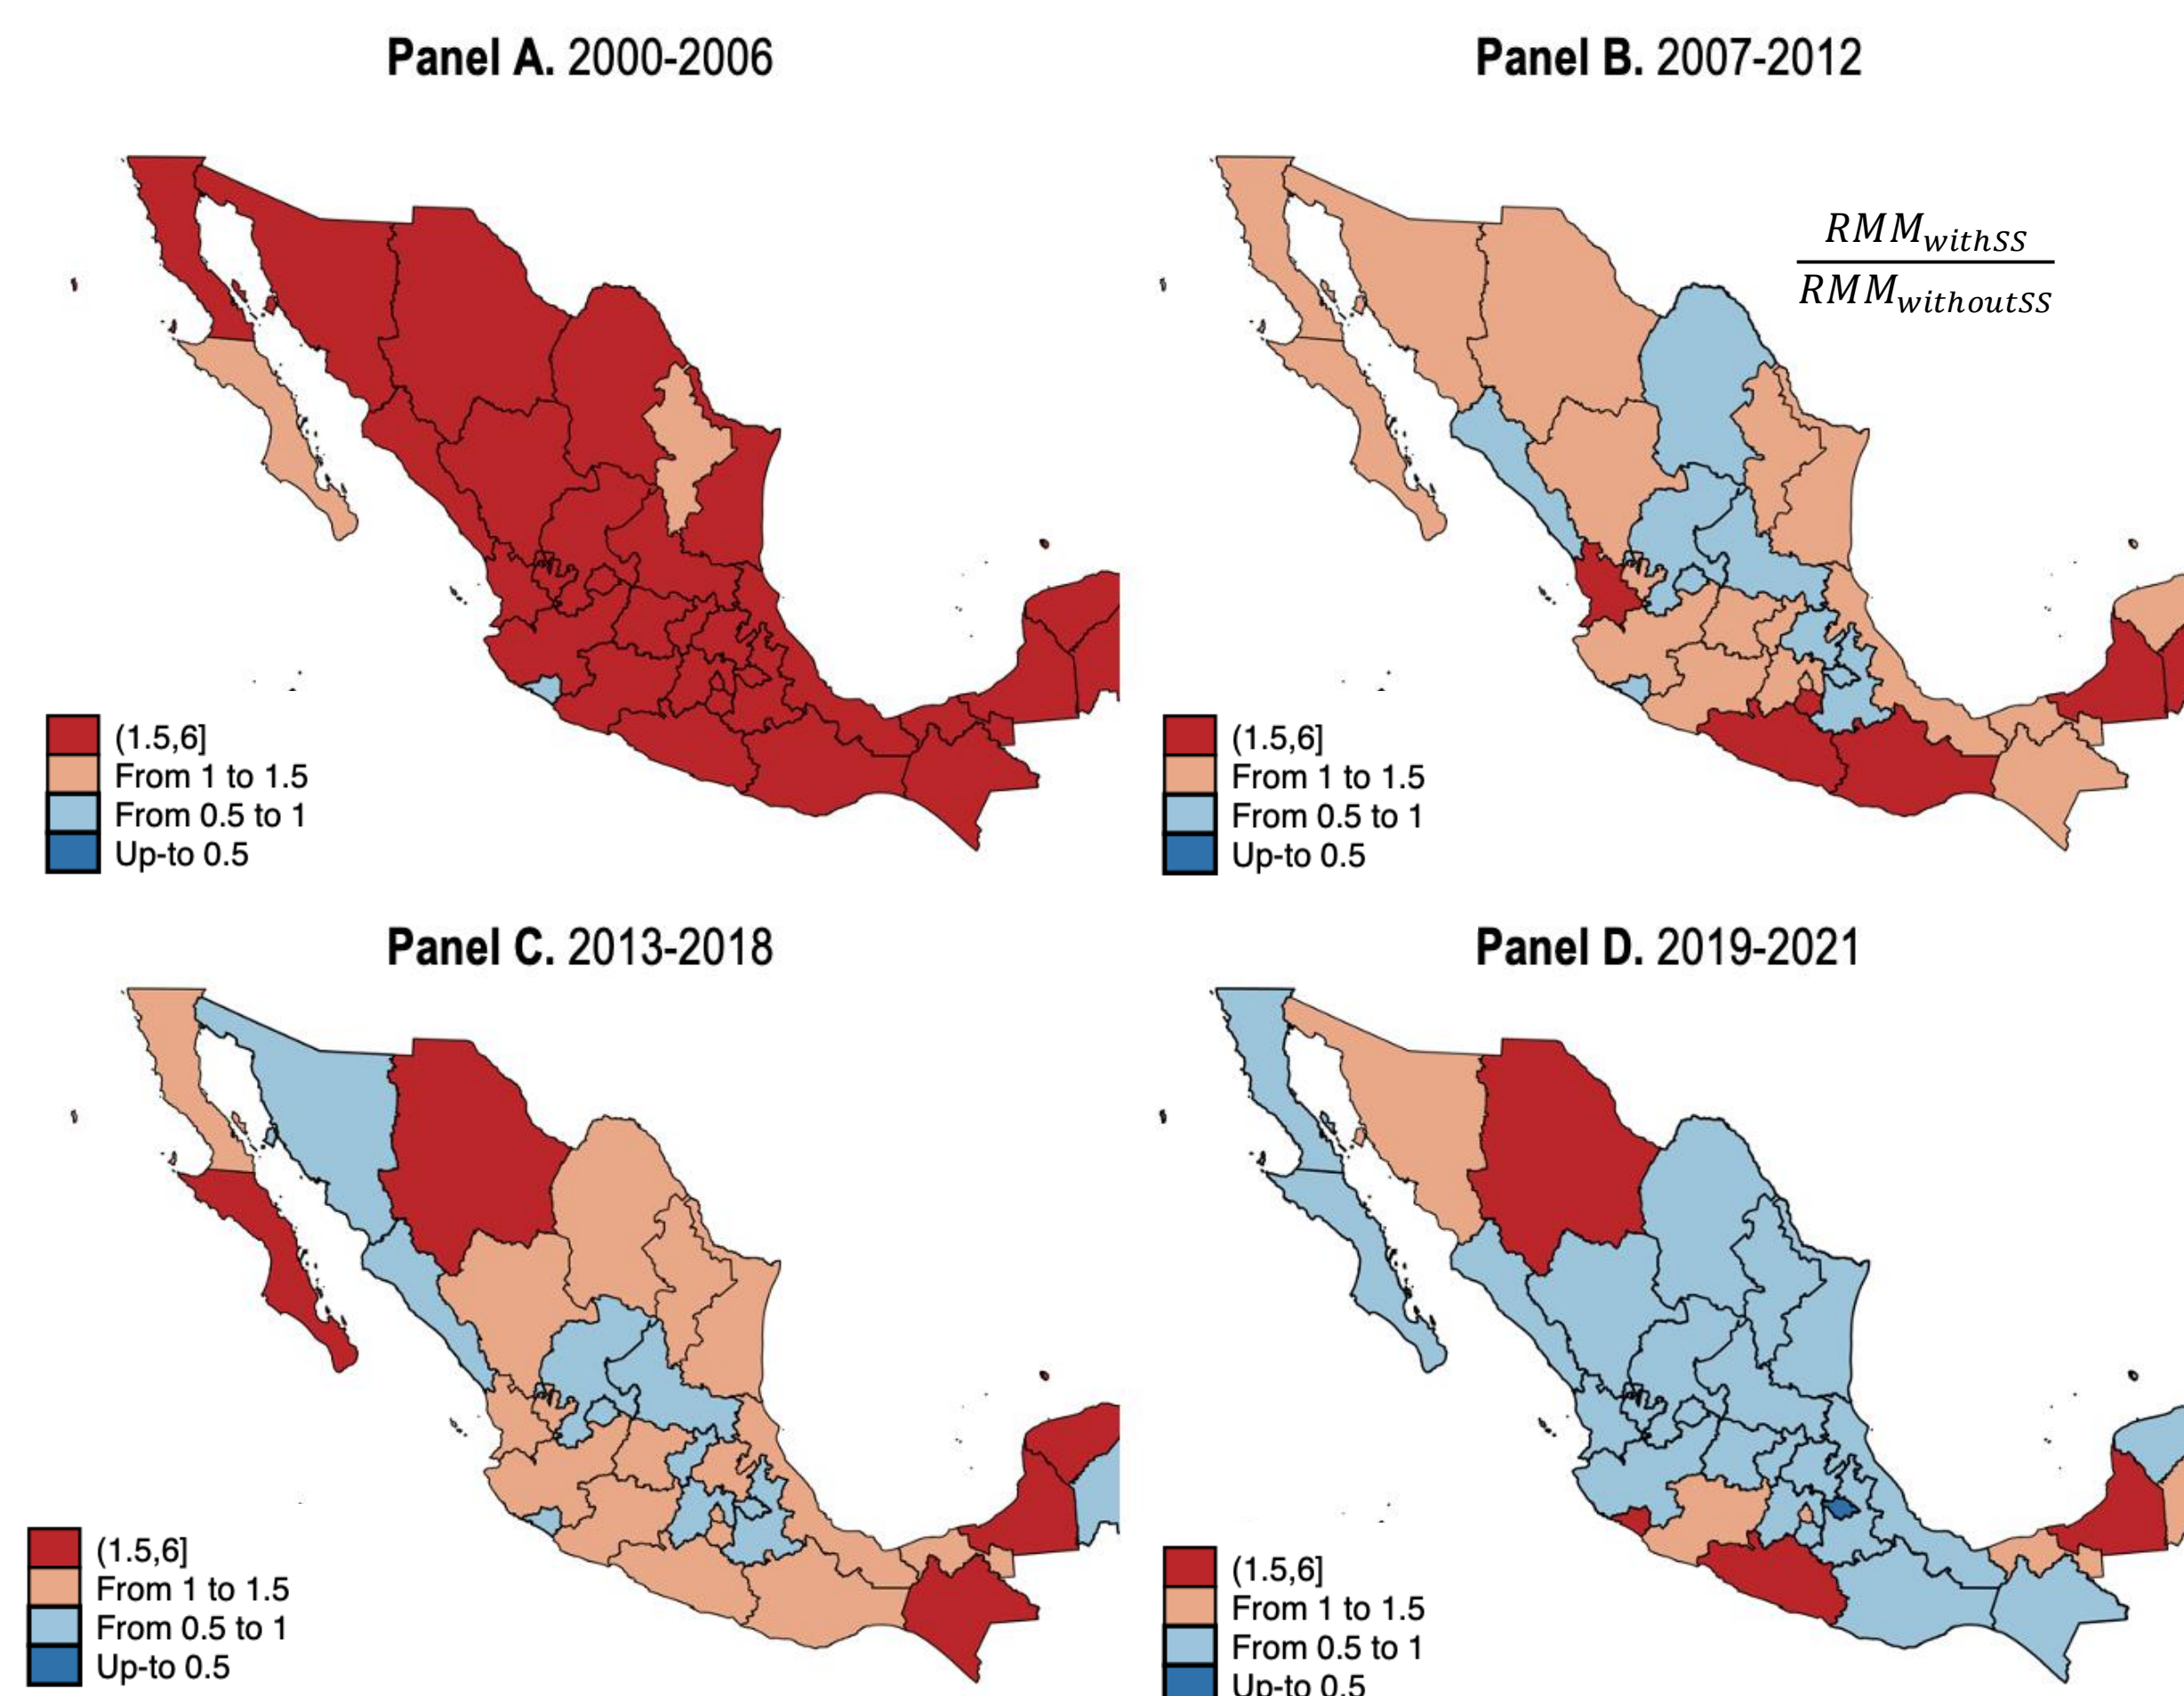

**Fig 2. Distribution of maternal deaths by social security status in Mexico from 2000 to 2021**

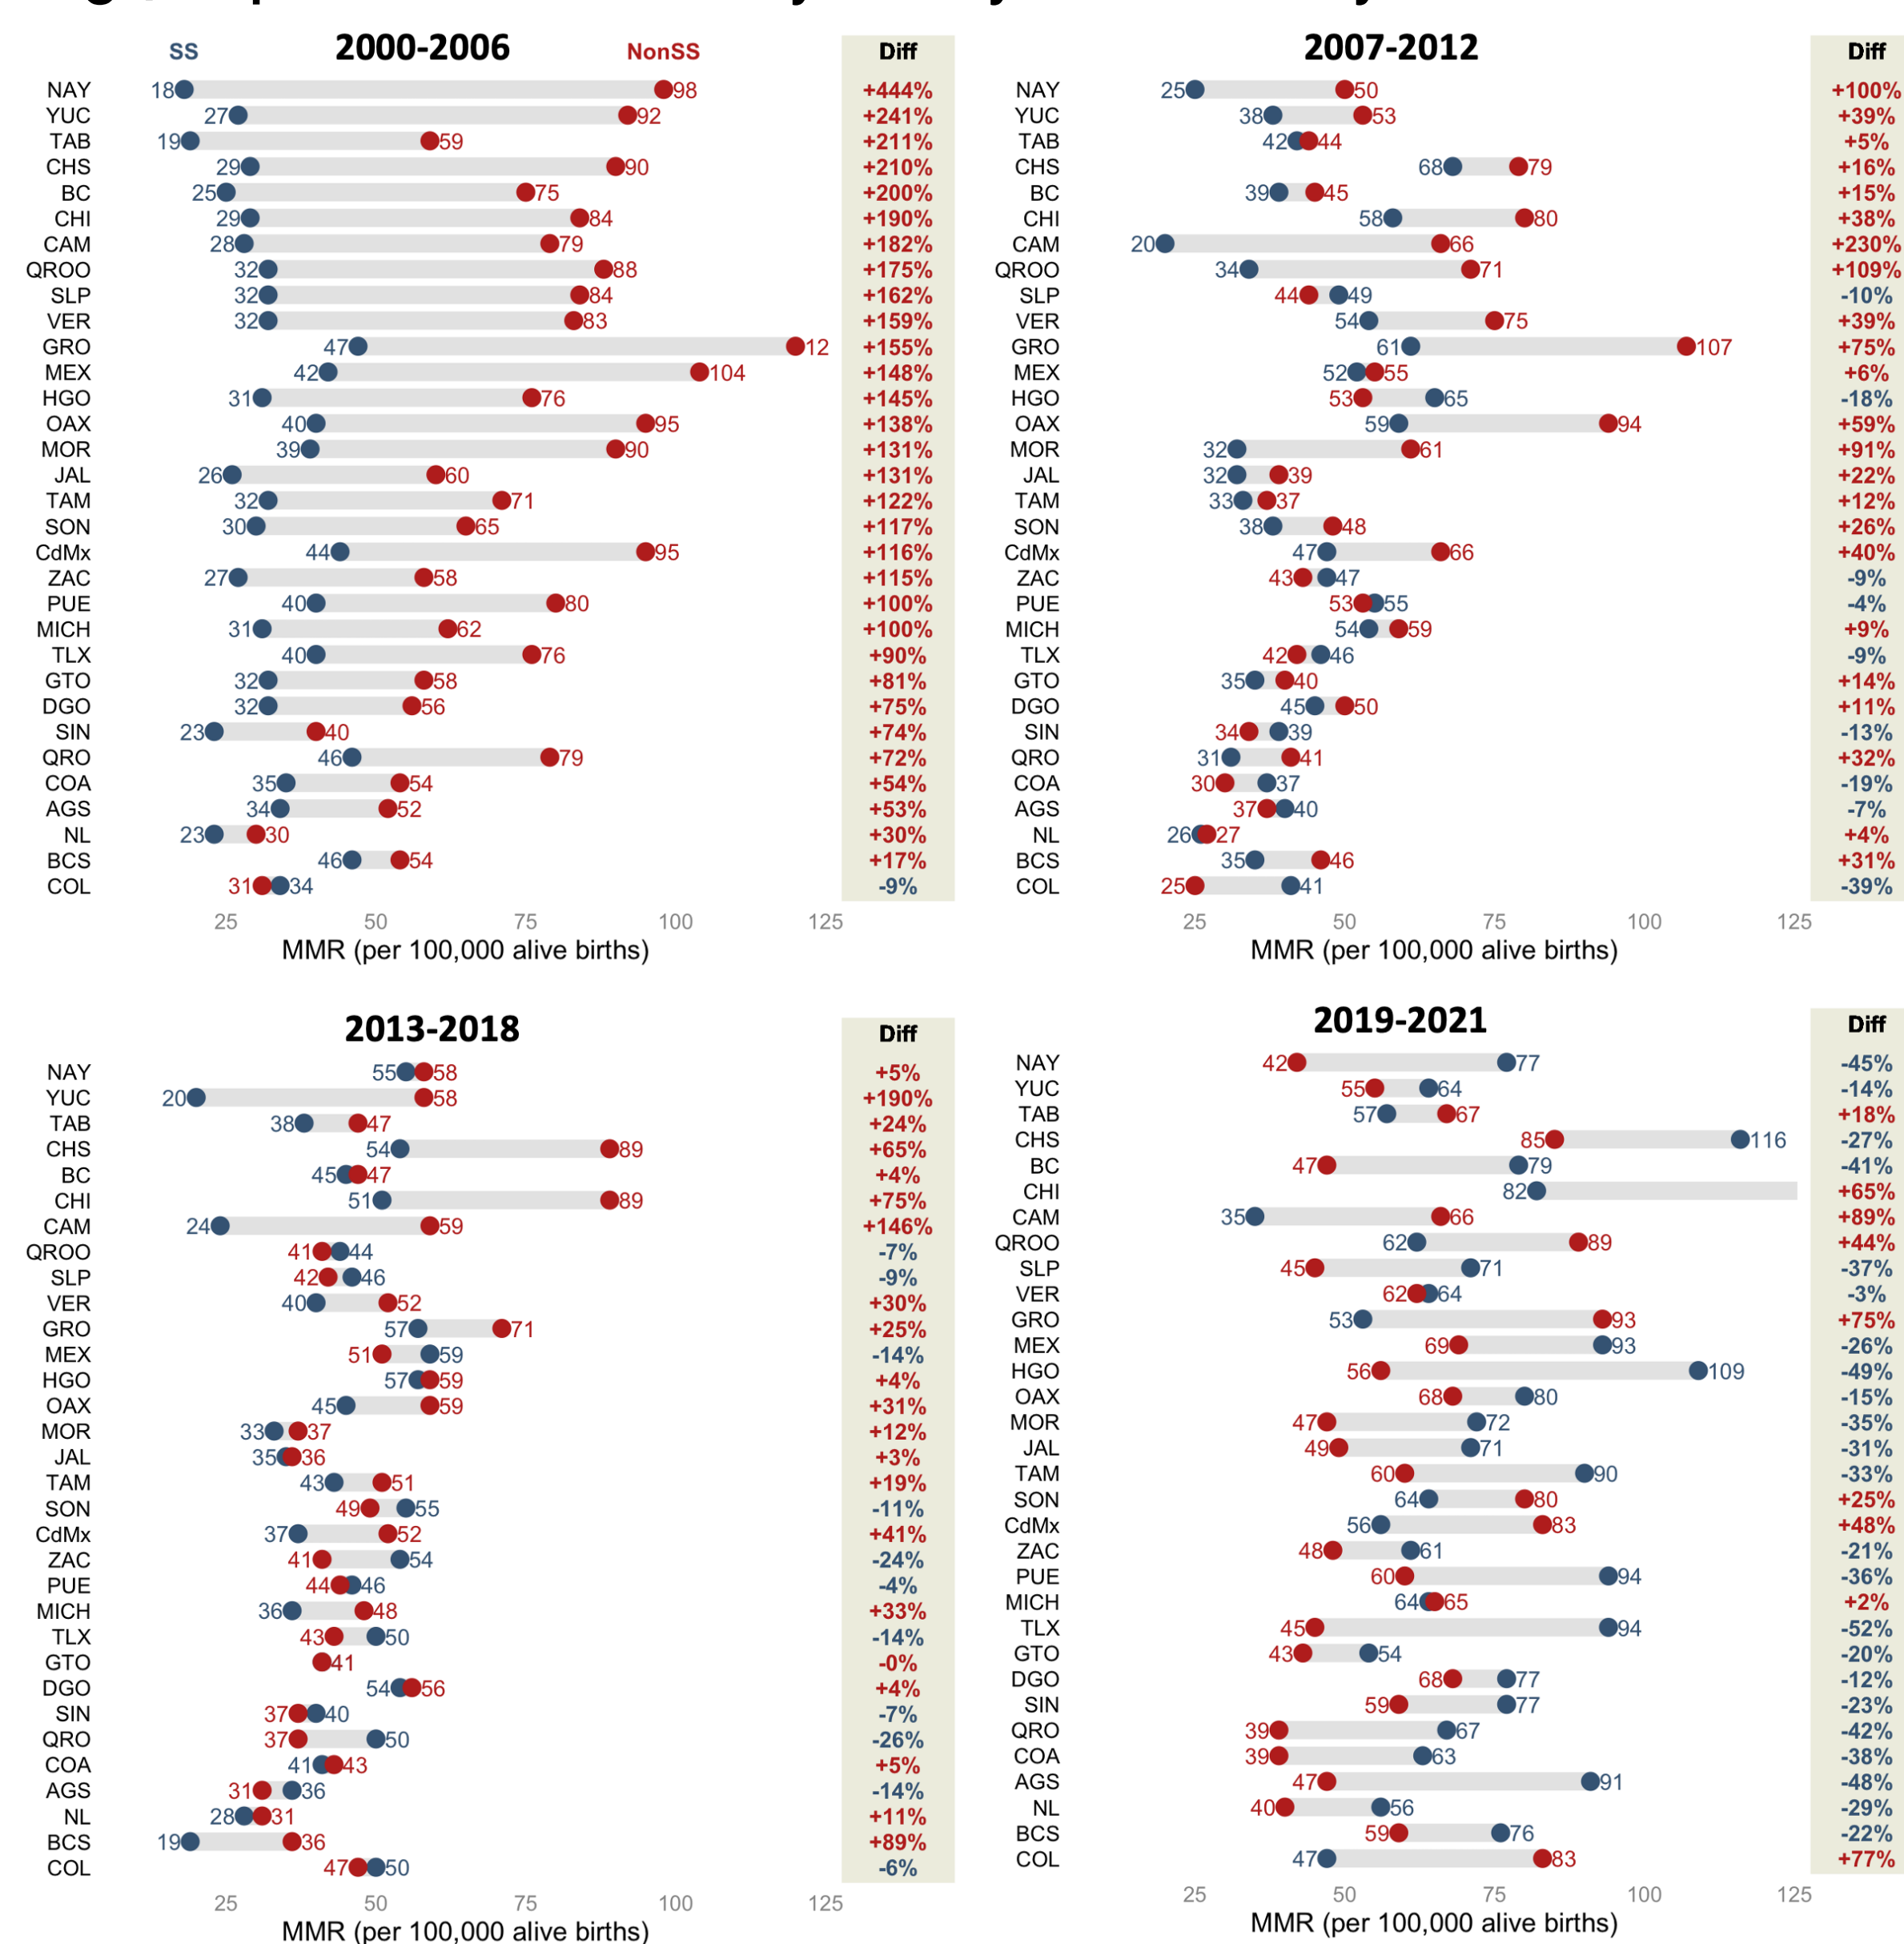

## Since 2019, a transition to higher ratios of maternal mortality in the population with social security has been observed in most of Mexican states

- An accelerated growth in populations with and without social security was observed in the period 2019 - 2021.
- The observed pattern in MMR is a wide gap in the first period, then a contraction of the gap in the two subsequent periods, and finally a transition to higher MMRs in the population with social security.

**Fig 3. Ratio of maternal mortality ratio by social security status in Mexico from 2000 to 2021.**

**Fig 4. Gap of maternal mortality ratio by social security status in Mexico**

## Conclusions

To address the inequalities in access to maternal healthcare services associated to health system fragmentation it is necessary to understand the population profile and the MMR trends among populations with and without social security.
